CHAPTER I

INTRODUCTION

INTRODUCTION

The thesis presented herein can be said to be only the beginning of research work on this particular subject because the field covered is practically without limit, but the method formulated and adopted by the writers is applicable to any of the many forms of tile and other fireproofing materials used in building construction at the present time. The problem presented for solution was mainly the design of apparatus which would satisfactorily and accurately measure the heat transmitted through fireproofing materials, followed by the application of the apparatus to as many forms of tile as our limited time would permit.

As no apparatus, known to the writers, had previously been designed for this particular purpose, the attack on the problem was purely experimental, and the design, as first adopted, demonstrated conclusively where the improvements were necessary. Accordingly, the apparatus was rebuilt, and in the succeeding tests gave satisfactory results.

The application of the apparatus has been made on only four samples, but the samples were chosen with the idea of compiling data on a few varied forms, and although no definite conclusions can be drawn from the information obtained, yet enough can be gleaned to give a few concrete ideas as to their relative value.

The writers wish to extend their thanks to Mr. Johnson, Vice-President of the National Fireproofing Company, for the samples that were tested, and to the Engineers of the Underwriters' Laboratories, who extended valuable assistance at various times.

The thesis presented herein can be said to be only the beginning of research work on this particular subject because the field is so vast and the material is so abundant that it is practically impossible to cover it in a single volume. The writers are applying to any of the many forms of life and other living organisms the principles used in building construction at the present time. The problem presented for solution was merely the design of apparatus which would satisfactorily and accurately measure the heat transmitted through fireproofing materials, followed by the application of the apparatus to as many forms of life as our limited time would permit.

As no apparatus, known to the writers, had previously been designed for this particular purpose, the design of the problem was largely experimental, and the design, as first stated, was somewhat completely new. Accordingly, the apparatus was built, and in the succeeding tests gave satisfactory results. The application of the apparatus has been made on only four samples, but the results were in line with the idea of comparison. A few varied forms, and although no definite conclusions can be drawn from the information obtained, yet enough can be gleaned to give a few concrete ideas as to their relative value.

The writers wish to extend their thanks to Mr. Joseph, Vice President of the National Fireproofing Company, for the samples that were tested, and to the Engineers of the Underwriters' Laboratories, who extended valuable assistance at various times.

- C. Calorimeter, etc.

FURNACE AND FURNACE PANELS.

FURNACE
CONSTRUCTION

The furnace is built of heavy fire brick, laid in fire-clay mortar and is shown by a photograph in Chapter VI. The outer face is made of pressed brick, laid in ordinary plaster mortar. At the four vertical edges of the furnace, heavy three inch angles are provided, the two front and the two rear being connected at both bottom and top by heavy bolts. The entire setting rests on heavy steel framework which in turn is mounted on heavy casters, which permit and facilitate movement of the furnace. For the escape of burned gases, eight openings are provided in the arch, averaging in dimensions $3\text{-}3/8$ inches by 4 inches. At each side of the furnace four openings, each 4 inches by 4 inches, are provided for the gas burners. Two small holes, one on each side, are provided for the insertion of furnace pyrometers.

HEATING

The furnace is heated by eight burners, four on each side, each burner being made of three-fourths inch pipe, with controlling valve attached, connected to a one and three-quarter inch pipe, connected to the gas supply main. Air is supplied from an air blower to all burners through two and one-half inch pipes, with controlling valve attached at all burners. At the bottom burner on each side a small pilot light is provided. The flames of all the burners impinge on the middle of the back of the furnace and the heat is then reflected to the middle of the test wall.

PANEL
FRAME-WORK

For the testing of the samples, a test wall in the form of a steel frame, divided into three panels, was constructed. Under the middle panel, four casters were provided, which permitted movement of the whole frame. The middle panel was filled solid with large gypsum blocks and was used as a blank wall before the test panel was moved into place. The two end panels were used for mounting the test samples. At the four corners of each test panel holes were tapped and drilled for one-half inch pipes, which served as supports for adjustable frame-work of the calorimeter.

The furnace is built of heavy brick, laid in
 brickwork, and is shown by a photograph in
 Figure 1. The entire furnace is covered by a
 brick, laid in ordinary brickwork, at the top, and
 of the furnace, being three inches thick, and the
 and the two lower sections at both ends, and the
 brick, the whole being covered by a brick, laid in
 brick, laid in heavy brick, and a brick, laid in
 of the furnace, and the brick, laid in brick, laid in
 are provided in the brick, every inch of brick, laid in
 inches, at each end of the furnace, and a brick, laid in
 4 inches, are provided for the furnace, and a brick, laid in
 each side, are provided for the furnace, and a brick, laid in

The furnace is built of heavy brick, laid in
 brickwork, and is shown by a photograph in
 Figure 1. The entire furnace is covered by a

 4 inches, are provided for the furnace, and a brick, laid in
 each side, are provided for the furnace, and a brick, laid in

For the testing of the furnace, a test wall in the
 form of a steel frame, divided into three parts,
 was constructed. Under the brick wall, the
 of the furnace, which permitted movement of the brick wall,
 the brick wall was filled with brick, laid in brick,
 and as a brick wall, the test wall was divided into three
 and panels were used for testing the test wall, and the
 of the test wall, and the test wall, and the test wall,
 inch plate, which served as support for the test wall, and the
 of the test wall.

PYROMETERS AND THERMOMETERS

PYROMETERS

The pyrometers used in the tests that follow, consisted of four platinum iridium, and three copper constantan couples. The platinum couples consisted of two wires which were fused together at one end and soldered to their leads at the other end. The fused end was designated as the hot junction and the soldered end as the cold junction. In the case of the copper couples the hot junction was fused together but at the cold junctions the wires and the leads were placed in a glass tube containing mercury. In actual tests, the couples were placed in clay tubing at the hot junction end, and in asbestos rope, from the clay tubing to the cold junction, in order to protect the wires from being crossed or coming into contact with any metal.

CALIBRATION

In calibrating, the metal used was heated above its melting point, and the hot junction placed in the center of the molten metal, while the cold junction was placed in small glass tubes in ice. The leads attached to the couple extended to the particular galvanometer used. The metal was then allowed to cool while readings of the galvanometer were taken at intervals of every fifteen seconds until solidification occurred. A curve was then plotted in every case between galvanometer readings and time, and the freezing point taken as shown where the galvanometer readings were constant. The curve plotted showed a decided straight line at the freezing point in every case. The freezing points of the metals used were taken from the Government Reports on the freezing point of pure metals. Knowing the melting points of the metals used and the corresponding galvanometer readings, a calibration curve was drawn for each couple, plotting temperatures as ordinates and millivolts as abscissa. The calibration data will be found in Chapter IV and the curves in Chapter V.

THERMOMETERS

The thermometers used in measuring the temperature of water at entrance and exit in the calorimeter and annular ring were obtained from the physics department. All were calibrated to a standard thermometer, and all readings given in the test record are corrected.

APPARATUS

The thermometers used in the tests are of the following type: The thermometers consisted of four platinum resistance coils, each of which was fused to one end and soldered to the other end. The leads at the other end were designed as the hot junction and the soldered end as the cold junction. In the case of the copper samples the hot junction was fused together but at the cold junction the wires and the leads were placed in a tube containing mercury. In actual tests, the samples were placed in clay tubing at the hot junction end, and in a separate tube, from the clay tubing to the cold junction, in order to protect the wires from being crossed or coming into contact with any metal.

CALIBRATION

In calibrating the metal used was silver, its melting point, and the hot junction was placed in the center of the molten metal. While the cold junction was placed in small glass tubes in ice. The leads attached to the coils extended to the particular galvanometer used. The cold junction was always to cool while readings of the galvanometer were taken at intervals of every fifteen seconds until solidification occurred. A curve was then plotted in every case between galvanometer readings and time, and the freezing point t_f was ascertained where the galvanometer readings were constant. The curves plotted showed a typical S-shape of line at the freezing point in every case. The freezing point of the metals used were taken from the Government tables for the freezing point of pure metals. Knowing the melting points of the metals used and the corresponding galvanometer readings, a calibration curve was drawn for each coil, plotting temperatures as ordinates and galvanometer readings as abscissas. The calibration data will be found in Chapter IV and the curves in Chapter V.

THE THERMISTERS

The thermometers used in the tests are of the following type: The thermometers consisted of four platinum resistance coils, each of which was fused to one end and soldered to the other end. The leads at the other end were designed as the hot junction and the soldered end as the cold junction. In the case of the copper samples the hot junction was fused together but at the cold junction the wires and the leads were placed in a tube containing mercury. In actual tests, the samples were placed in clay tubing at the hot junction end, and in a separate tube, from the clay tubing to the cold junction, in order to protect the wires from being crossed or coming into contact with any metal.

THE CALORIMETER

CHOICE OF DESIGN The design of apparatus for the measurement of the heat transmitted through the various forms of tile, presented a problem which was more difficult of solution than the accompanying design would seem to indicate. It was only after careful analysis of the conditions that were to be met with in the different tests that the particular design was chosen. Subsequently, it was found necessary to make some changes that would more perfectly meet the requirements. This design was chosen because it presented the most feasible means of obtaining results that would be accurate.

THE DESIGN The design of the calorimeter embodied the idea of having a thin layer of water pass through a definite channel from A to B as shown in the sketch. On account of the thinness of the layer of water, a uniform temperature prevailed throughout. The product of the difference in temperature at entrance and exit, and the weight of water represents the amount of heat absorbed by the water during passage. The design of the calorimeter is shown in Sketch No. I. It was made of #28 B and S gauge copper sheet with all joints carefully and tightly soldered. Short pieces of copper tubing were used in providing passage ways for the pyrometers. Short brass nipples three-eighths inches in diameter were well soldered at entrance and exit for the attachment of the supply and discharge pipes.

THE ORIGINAL APPARATUS The insulation originally provided for the calorimeter, consisted of three layers of cork arranged as in Illustration No. II. The layer flush with the face of the calorimeter was of one-half inch finely ground and pressed cork, in the center of which a recess large enough for the insertion of the calorimeter was carefully turned. In back of this was provided two layers of cork, each layer two inches in thickness, of coarse heavy stock and pressed with natural cork oil. The three layers of insulation were held in position by a galvanized iron vessel, the edges of which did not quite extend to the outer edge of the thin layer of cork. Short brass screws were set through the vessel into this layer. As a tight fit was provided for the other layers, the entire insulation was held in the vessel rigidly. A circle eight inches in diameter was cut in the back of the vessel, thereby exposing the back layer of the insulation. This was considered necessary, in order that no heat could be conducted from the vessel to the water pipes, which pass through the cork insulation, from the calorimeter to the fittings provided for the measurement of the temperatures of the water at entrance and exit. The fittings, placed as close as was practicable to the back of the vessel, consisted of an elbow and a tee insulated by a mold of Kiesel Guhr and gypsum. For the insertion of the pyrometers, holes were drilled through the cork in coincidence with the holes in the calorimeter, so that the pyrometers

THE CALORIMETER

Office of the design of apparatus for the measurement of the heat transmitted through the various forms of air, present in a building, and more difficult of solution than the accompanying design, would seem to indicate. It was only after careful study of the conditions that were to be met with in the different cases that the particular design was chosen. Subsequently, it was found necessary to make some changes that could more perfectly meet the requirements. This design was chosen because it presented the most feasible means of obtaining results that would be accurate.

THE DESIGN The design of the calorimeter embodied the idea of having a thin layer of water between the definite channel from A to B in the shape of a cylinder, the thickness of the layer of water, a uniform thickness, provided throughout. The product of the difference in temperature of the entrance and exit, and the weight of water represents the amount of heat absorbed by the water during passage. The design of the calorimeter is shown in Section No. 1. It was made of 1/2 inch and 3/4 inch copper sheet with all joints carefully and tightly soldered. Short pieces of copper tubing were used in providing passages for the pyrometers. Short brass rods as three-eighths inches in diameter were well soldered at entrance and exit for the attachment of the supply and discharge pipes.

THE ORIGINAL APPARATUS The insulation originally provided for the calorimeter, consisted of three layers of cork arranged as in illustration No. 2. The inner layer was 1/2 inch thick, the middle layer was of 1/2 inch thick, and the outer layer was of 1/2 inch thick, pressed cork, in the center of which a recess large enough for the insertion of the calorimeter was carefully formed. In back of this was provided two layers of cork, each layer two inches in thickness, of coarse heavy stock and was held in position by a 1/2 inch rod. The edges of which did not quite extend to the outer edge of the thin layer of cork. Short brass wires were attached to the other vessel into this layer. As a tight fit was provided for the other layers, the entire insulation was held in the vessel rigidly, a circle eight inches in diameter was cut in the back of the vessel, thereby exposing the back layer of the insulation. This was considered necessary, in order that no heat could be conducted from the vessel to the water pipes, which was through the cork insulation, from the calorimeter to the fitting provided for the measurement of the temperature of the water at entrance and exit. The fitting, shown as close as was possible to the back of the vessel, consisted of a 1/2 inch and a 3/4 inch insulated by a coil of 1/2 inch Galv. and 1/2 inch for the insertion of the pyrometers, holes were drilled through the cork in coincidence with the holes in the calorimeter, so that the pyrometers

had a straight passage through the insulation and calorimeter to the sample form.

INSULATION FAILURE During the test, which is not recorded in these contents, the cork adjacent to the tested sample was burned out, and new means of insulation had to be devised. The burning of this insulation spoiled all results of the test, but gave valuable information as to the proper means of insulation and the form it should take.

ANNULAR RING The method of insulation decided upon was two-fold in its application and provided a means of a more thorough insulation than that used in the first test. An annular ring was constructed of the same material as the calorimeter and is shown in illustration III. This was placed around the calorimeter with one-eighth inch clearance. At one side, the ring was divided with a copper strip, and water supply pipes were placed above and below this division wall, to insure the ring being full at all times. The discharge pipe was placed on the opposite side. Fittings for the measurement of the temperature of the entrance and exit water were provided similar to those on the calorimeter. At the outer edge of the annular ring a strip of copper ribbon was placed, serving as an adjunct in dissipating the heat away from the insulation.

RESULTS OBTAINED The addition of the annular ring as a means of insulation for the calorimeter accomplished two results:

1. It protected insulation in back of the calorimeter and the ring from destruction;
2. It made a perfect insulation on the outside edges of the calorimeter.

The first of these results is obvious, because the entire face exposed to the heated sample was thoroughly cooled by the water passing through the calorimeter and the ring, and therefore sufficient heat could not be transmitted to the insulation to cause it to be destroyed. The second was accomplished by creating a perfect heat balance between the calorimeter and the annular ring. Through adjustment of the valves at the respective exits, the difference in temperatures at entrance and exit of the calorimeter and the annular ring was the same and equal. When this condition had been reached no heat was being transmitted to or drawn away from the calorimeter and therefore the amount of heat absorbed in the calorimeter was only that transmitted through its exposed face.

had a straight passage through the insulation and calorimeter to the sample form.

During the test, which is not recorded in these contents, the work object in the calorimeter was carried out, and the result of this investigation was all results of the test, but gave valuable information as to the proper means of insulation and the form it should take.

THE METHOD OF INSULATION. The calorimeter was placed in the calorimeter and provided a means of a more thorough insulation than that used in the first test. An insulating ring was constructed of the same material as the calorimeter and in a similar fashion. This was placed around the calorimeter with its eight inch diameter. At one side, the ring was divided with a copper wire, and water supply pipes were placed above the calorimeter division wall, to have the ring being full at all times. The discharge pipe was placed at the opposite side. Fittings for the measurement of the temperature of the entrance and exit water were provided similar to those on the calorimeter. At the outer edge of the insulating ring a strip of copper ribbon was placed, serving as a gasket in displacing the heat away from the insulation.

RESULTS. The edition of the calorimeter was a means of insulation for the calorimeter accomplished two results:

1. It protected insulation in back of the calorimeter and the ring from destruction;
2. It made a perfect insulation on the outside edges of the calorimeter.

The first of these results is obvious, because the entire face exposed to the heated sample was thoroughly protected by the water ring through the calorimeter and the ring, and therefore no heat could be transmitted to the insulation in back of the calorimeter. The second was accomplished by means of the distance between the calorimeter and the insulating ring. This distance of the valves at the respective ends, the distance in further at entrance and exit of the calorimeter and the insulating ring was the same as usual. The heat was being reduced no heat was being transmitted to the calorimeter in the calorimeter and therefore the amount of heat received in the calorimeter was only that transmitted through the sample form.

MOUNTING

At the points where the pipes to the entrance and exit of the annular ring passed through the back of the galvanized iron container, the metal was carefully cut away for a distance of approximately two and one-half inches in all directions, thus avoiding any error due to heat being conducted from the container to the water pipes. The annular ring was carefully mounted, in the same manner as the calorimeter with its face in the same plane as the calorimeter. Asbestos and Kiesel Guhr was packed solidly in the one-eighth inch clearance between the calorimeter and the ring to keep heat from passing between the two containers.

ADJUSTING
IN PLACE

The calorimeter was held in place on the face of the sample by means of a frame-work made of iron pipes and pipe fittings. The portions that were to move through appreciable distances were threaded and fitted with nuts to securely lock the frame-work when once it had been adjusted. By means of this frame-work fine adjustments could be made in all directions. The circular band shown in the photograph was the immediate support of the shell of the calorimeter and by its aid a further adjustment to and from the test panel, and also in a rotary direction was obtained. The latter was of great importance in placing the pyrometers in position. The frame-work operated satisfactorily at all times and gave a rigid and solid protection to the pyrometers, which might have been injured had any movement occurred.

At the point where the pipe in the entrance
and exit of the smaller vessel crossed the main

the back of the gaily mixed from container, the vessel was
filled out away for a distance of approximately two feet in inches
in all directions, thus avoiding any error due to local
contact from the container to the water level. The smaller
was carefully washed, in the same manner as the container with
its face in the same plane as the container. A distance of
Guth was placed solidly in the one-eighth inch distance between
the container and the ring to keep that two inches between the
two containers.

ADJUSTING The adjustment was held in place in the form of
IN PLACE the as the up means of a thermometer and of

from the and the fitting. The adjustment was
was to have brought up to the level of the container and
filled with water to exactly level the container when it had
been adjusted. By means of this device the adjustment
could be made in all directions. The adjustment was
photo, and was the immediate support of the level of the container
and by it a further adjustment to the level of the container,
also in a vertical direction was obtained. The level was of
great importance in placing the pyrometer in position. The three
not placed satisfactorily at all times and gave a slight
solid protection to the pyrometer, which might have been improved
and any movement occurred.

THE WATER SUPPLY

THE TANK A tank having a capacity of approximately five gallons was placed on a standard near the ceiling. The supply of water was obtained from the city mains which were connected to the tank. The discharge to the calorimeter and the annular ring was through half inch pipe. An overflow pipe two inches in diameter was provided to keep the water in the tank at a constant level. The supply line was connected with the calorimeter and annular ring by three-eighths inch patrol hose.

**DISCHARGE
FITTINGS** The discharge fittings for the calorimeter consisted of half-inch pipe with a one-half inch gate-valve placed in the line to permit adjustment of flow. This was placed on a standard in such a way as to insure a constant head on the system. The exit from the annular ring consisted only of a length of three-eighth inch hose with a valve attached for adjustment of flow.

**ADJUSTMENT
OF FLOW** This arrangement gave a constant head on the calorimeter, which was of prime importance. The supply to the tank was adjusted in every test so that the overflow pipe was constantly discharging water. As the position of the discharge fitting from the calorimeter was the same throughout each test, the head was constant and therefore the discharge the same for all periods.

THE WATER TREAT

The first thing I saw when I stepped out of the plane was a view of a valley with a river and some hills. The valley was filled with a dense forest of tall, thin trees. The river was a narrow, winding stream that flowed through the center of the valley. The hills were low and rounded, with a few small trees growing on them. The air was fresh and cool, and the sun was shining brightly. I felt a sense of peace and tranquility as I looked out over the landscape.

As I walked along the river, I noticed that the water was very clear and clean. The banks were covered with a thick layer of grass and small flowers. The trees on the hills were mostly deciduous, with some evergreens scattered here and there. The overall scene was one of natural beauty and serenity. I took a few deep breaths of the fresh air and felt a sense of rejuvenation. The water in the river was so clear that I could see the bottom, which was covered with small stones and pebbles. The fish in the river were small and colorful, and they seemed to be swimming freely. The sound of the water flowing over the rocks was a soothing melody that filled the air.

The water in the river was not only clear but also very pure. I took a small cup of water and drank it, and it tasted so good. The water was so clean that I could see the bottom of the cup. The fish in the river were so small that they looked like tiny jewels. The overall scene was one of natural beauty and serenity. I took a few deep breaths of the fresh air and felt a sense of rejuvenation. The water in the river was so clear that I could see the bottom, which was covered with small stones and pebbles. The fish in the river were small and colorful, and they seemed to be swimming freely. The sound of the water flowing over the rocks was a soothing melody that filled the air.

CHAPTER II

The purpose of this chapter is to set forth the general principles which should govern the conduct of the investigation of the cause of the accident.

1. The investigation should be conducted in a systematic manner.

2. The investigation should be conducted in a thorough manner.

3. The investigation should be conducted in a fair and impartial manner.

4. The investigation should be conducted in a timely manner.

The purpose of this chapter is to set forth the general principles which should govern the conduct of the investigation of the cause of the accident.

CHAPTER III

GENERAL PLAN OF INVESTIGATION

The purpose of this chapter is to set forth the general principles which should govern the conduct of the investigation of the cause of the accident.

The purpose of this chapter is to set forth the general principles which should govern the conduct of the investigation of the cause of the accident.

CHIEF OF POLICE

GENERAL INVESTIGATIVE DIVISION

GENERAL PLAN OF INVESTIGATION

ESSENTIAL
FEATURES

The general plan of investigation of each sample was practically the same, the essential features in each test being the determination of the following:

1. Physical characteristics before exposing to fire;
2. Time and temperature for saturation at all depths for different furnace temperatures;
3. Heat transmitted per unit of area at these saturation points for the different furnace temperatures;
4. Physical characteristics after exposure to fire.

After accurate measurements of each sample had been taken, the form was closely examined for flaws, cracks, scale, broken edges, holes, scabs, lime spots, marks of unequal kiln-heating, hardness, color, etc. Photographs of each sample tested were taken, which are attached, in order to clearly identify these characteristics. The sample was then set in place in the center of the test panel and the calorimeter and pyrometers installed and properly adjusted, and the water and electrical connections made.

OPERATION

The solid panel of the test wall was then rolled in front of the furnace and the burners set in operation. After the furnace temperature had been properly adjusted, the test panel was rolled in front of the furnace and set flush against its edges. Readings of the pyrometers were taken and subsequently at definite intervals throughout the test. As soon as the temperatures throughout the sample had become constant, for a given furnace temperature, the flow of water through the annular ring and the calorimeter was adjusted to give the same difference in temperatures at entrance and exit. Readings of these temperatures were then taken and recorded. The discharge was then measured for a period of time sufficient in length to avoid errors usually made in an operation of this nature. When the readings of the pyrometers and the thermometers had remained constant for a period varying from thirty minutes to one hour at the given definite temperature in the furnace, the burners were adjusted to give the next temperature desired in the test, and the same procedure followed. Each sample was tested at three different furnace temperatures in this manner, each temperature being maintained until the saturation point at that temperature had been reached. The constancy of the pyrometer and thermometer readings, for a reasonable length of time, indicated that the saturation point had been reached for that particular furnace temperature. In order that the equation of the curve showing the heat transmitted

be definite, it was deemed best to test each sample at three different furnace temperatures, these temperatures ranging from approximately 1200 to 2000 degrees Fahrenheit.

After the saturation point at the highest temperature had been reached and maintained for a reasonable length of time, the gas supply to the furnace was shut off and the furnace and the test panel allowed to cool slowly to normal temperature. The sample was then removed from its setting and its characteristics noted. In addition to the previously mentioned characteristics the following qualities were noted: Depth and degree of calcination and disintegration, depth of vitrification, checking and cracking, defective depth of injury, falling away of faces and edges, and the general change in the texture of the tile. Photographs of each sample after exposure to fire were taken and are shown in Chapter VI.

in addition, it was observed that in some cases the

PYROMETER CALIBRATION DATA

Couple No.	126	128	130	131	Series 5
Melting Point of Tin,	449	449	449	449	449
Voltage (in millivolts)	2.22	2.21	.79	.73	7.30
Melting Point of Zinc	786	786	786	786	786
Voltage (in millivolts)	4.60	4.59	1.59	1.50	14.86
Melting Point of Copper	1981	1981	1981	1981	1981
Voltage (in millivolts)	14.32	14.29	4.9	4.65	

The above calibration was carried out with the use of Galvanometer #2, which was used in all of the measurements taken in the thesis. Pyrometer, Series 5, was used in connection and in series with a resistance box.

The data for curve #6, for couple Series 5 in connection with Galvanometer #3 and without resistance in circuit, is as follows:-

Voltage	Temp.
0.00	35
0.82	77
4.00	213
10.30	449

TEST NO. 1

FOUR INCH COMMERCIAL FORM
OF BUILDING TILE

The sample selected for test was of the ordinary form of commercial building tile with ridged outer surfaces taken at random from a large number of similar forms, but of such quality as to represent an average tile in size, nature of structure, density, color and hardness. Before actual exposure to fire the physical characteristics of the sample were noted in order to afford a comparison with the characteristics shown after exposure. Photographs were taken in order to more closely accentuate the points of difference. The measurements of the component parts of the sample are shown on Illustration No. V.

FROM EACH OF THE

THE FOLLOWING

The sample selected for test was of the
 ordinary form of commercial quality which
 is most common in the market.
 Large number of similar forms, but of small
 size, as is represented in the figure in
 figure 1, structure, density, color and
 weight, before actual exposure to the light
 characteristics of the sample were noted in
 order to obtain a comparison with the character-
 istics of other samples. The photograph was
 taken in order to more closely determine the
 nature of differences. The measurements of the
 component parts of the sample are shown in
 illustration No. 7.

PHYSICAL CHARACTERISTICS BEFORE EXPOSURE

EXPOSED SURFACE The flange which was designated as that which would be exposed to the fire was smooth in appearance and was a deep tan in color over the entire surface. The ridges were uniform and equal in depth, with the exception of that part of the flange which was directly over the webs where they were still uniform in depth but not of the same width as the majority. The surface was uniform in texture and density with no evidence of foreign ingredients. The flange was hard and solid throughout, devoid of all cracks, and gave forth a sharp metallic sound when struck.

UNEXPOSED SURFACE The unexposed surface of the sample was fairly smooth with uniform and equal depths in the ridges. In two places the ridges were slightly broken and on one corner a small chip had been broken off. A few small air holes were present but none had any appreciable depth. The entire interior of the form was very smooth, had no air holes, and was uniform in texture.

THE ENDS AND WEBS The ends of the sample were rather rough, and the webs were slightly misshaped, probably due to unskillful handling of the molded form preliminary to kiln-drying. The ends, sides and flanges were at right angles in all places and the whole presented a rectangular, symmetrical form.

SETTING After the physical characteristics had been noted, the sample was placed in one end of the test wall with both faces flush with the framework surrounding it. The calorimeter was then placed flush with the back of the sample, and the pyrometers located in their respective places. Two holes had previously been drilled in the back of the sample according to a template of the holes in the calorimeter, which facilitated the insertion of the pyrometers in their correct positions. Three pyrometers were inserted in the sample. One of these was placed on the inside surface of the unexposed face. The second was placed even with the inside surface of the unexposed face, while the third was placed on the outside surface of the unexposed face. This arrangement was chosen in order to give, if any, information regarding the value of the air space present in this particular form.

The things which were described as that which would be exposed to the fire was smooth in appearance and was a deep tan in color over the entire surface. The ridges were uniform and closely with the exception of that part of the thing which was directly over the hole where they were still visible in places in the same which as the majority. The surface was uniform in texture and density. It is no evidence of foreign materials. The things was not a solid structure, devoid of all cracks, and things which a sharp metallic sound was struck.

The exposed surface of the sample was fairly smooth with minor irregularities in the ridge. In two places the ridge was slightly broken and on one corner a small chip had been broken off. A few small air holes were present but none had any appreciable effect. The entire interior of the form was very smooth, had no holes, and was uniform in texture.

THE NEW YORK PUBLIC LIBRARY
ASTOR LENOX TILDEN FOUNDATION
500 5TH AVENUE
NEW YORK 17, N.Y.

The sample was placed over the unexposed face. The second was placed over the exposed face. The third was placed on the surface of the unexposed face. This arrangement was chosen in order to give, if any, information regarding the value of the air space present in this particular form.

THE TEST

OPERATION

As soon as the apparatus had been mounted on the tile form, the blank portion of the test wall was rolled into place in front of the furnace, and the furnace set in operation. When the temperature in the furnace had reached approximately 1200°F. The test wall was rolled until the end containing the sample to be tested was directly exposed to the fire. Readings of the furnace temperature were obtained by means of a furnace couple, placed in contact with the center of the exposed face of the sample. Readings of the pyrometers were taken at ten minute intervals. As the temperatures became constant throughout the sample, the flow of water through the calorimeter and the annular ring was adjusted to give the same difference in temperature between their respective entrances and exits. During the time when the readings of the pyrometers and the thermometers showed but slight variation, observations were frequently made in order to more closely judge the correctness of the temperatures taken as saturation points. When the readings of the pyrometers had become constant, final readings of the temperatures of the water, at entrance and exit, of the annular ring and the calorimeter, were taken and the rate of flow determined for a period of time sufficient in length as to insure a fair average value of the discharge.

TEMPERATURE
RISE

As rapidly as possible, the temperature in the furnace was then raised to 1600°F by adjusting the gas and air supply to the burners. Readings similar to those enumerated in the first part of the test were taken, and at the point of saturation the rate of flow, and the temperatures of the water passing through the annular ring and the calorimeter were noted. The burners were again adjusted so as to give a furnace temperature of 1800°F and readings taken at ten minute intervals until the saturation points at all depths were reached, when the rate of flow and the temperatures of the water passing through the calorimeter and the annular ring were noted.

SHUTTING
DOWN

After the last reading had been taken, the gas and air supply were shut off and the furnace allowed to cool slowly. When the test wall and furnace were thoroughly cooled the apparatus was taken down and the sample form of tile carefully removed. Careful observations of the physical characteristics of the sample were then made, and the points of difference, before and after exposure to fire, noted.

[illegible][illegible][illegible]

PHYSICAL CHARACTERISTICS AFTER EXPOSURE

EXPOSED SURFACE The color of the sample was practically the same, or at the most, only a slightly lighter shade. When tapped, it gave forth a hollow sound. The ridges, on the surface of the sample were unchanged. There was a slight crack three and one-half inches long over one web and another extending the entire length of the tile over the other web. There was a slight crack from the second web to the edge about two inches from the center of the tile.

UNEXPOSED SURFACE The unexposed surface was unchanged in color, texture and physical characteristics. This was due in all probability to the cooling effect of the calorimeter and the annular ring.

ENDS AND WEBS There was a crack all along one side which was irregular in direction and size. This crack was at the joining point of the exposed surface and the end. There was a slight crack across the middle of this end from the exposed face to the unexposed face. The other end had a heavy crack along its whole length, at the joining point of the exposed surface and the end. All the webs were cracked along the exposed face.

PHYSICAL ANALYSIS OF THE SAMPLE

The color of the sample was a slightly lighter
 blue, or at the most, only a slightly lighter
 shade. The texture of the sample was somewhat
 rough. The ridges on the surface of the sample were
 there was a slight crack along the center of the top
 one was a slight extension of the line of the top
 the other was a slight crack from the center
 web to the edge about two inches from the center of the top.

The exposed surface was somewhat irregular in color,
 texture and physical characteristics. This was
 due in all probability to the nature of the
 of the material and the manner in which it was

There was a crack all along the top edge of the
 material in a straight line. This crack
 was at the joining point of the two pieces of
 and the end. There was a slight crack across the middle of
 this one from the exposed face to the unexposed face. The other
 end had a heavy crack along its whole length, at the joining
 point of the exposed surface and the end. All the web were
 cracks along the exposed face.

TEST #1
Miscellaneous Data

Pyrometers:- #1 = calibration curve #2 for pyrometer #128
 #2 = calibration curve #3 for pyrometer #130
 #3 = calibration curve #5 for pyrometer #Series 5.

1st Saturation Point

Difference in temperature between entrance and exit of
 calorimeter = 2.12°F

Weight of water discharged = 57.48# in 12 minutes
 = 4.79# /min.

2nd Saturation Point

Difference in temperature between entrance and exit of
 calorimeter = 3.15°F

Weight of water discharged = 67.35# in 15 minutes
 = 4.49# /min.

3rd Saturation Point

Difference in temperature between entrance and exit of
 calorimeter = 4.86 F

Weight of water discharged = 54.625# in 15 minutes
 = 3.64# /min.

NOTE:-

The factor 1.834 used in the calculations of these tests is obtained as follows:-

The area of the calorimeter in square feet

$$= \frac{\pi \left(\frac{10}{12}\right)^2}{4}$$

$$= \frac{100\pi}{576}$$

$$= .545 \text{ sq. ft.}$$

As the heat transmitted through the samples is to be expressed in Btu/sq.ft. the factor to be used is

$$\frac{1.000}{.545} = 1.834$$

10.12.1

The factor 1.05 is used in the calculation of
 these data is obtained as follows:-

The area of the rectangle is square foot

$$\frac{10 \times 10}{12} = \frac{100}{12}$$

$$\frac{100}{12} = 8.33$$

$$= 8.74 \text{ sq. ft.}$$

As the area is less than the required
 it is to be increased in 5% the factor to be used is

$$1.05 \times 8.74 = 9.18$$

T E S T N O . 2

SAMPLE OF SOLID TILE.

This test was made on a sample
of solid tile, ground to an even
thickness as shown in the data.
The grade and quality of the tile
was the same as used in the three
other tests.

THE END

THE END

This last was one of the
of which the ground to be
known as shown in the
the ground and vicinity of the
was the same as used in the
other tests.

PHYSICAL CHARACTERISTICS BEFORE EXPOSURE
AND SETTING

SIZE OF SAMPLE The sample chosen for this test had an average thickness of 1.088 inches, the limits from which this average was taken being 1.07 inches to 1.12 inches. The width of the face was 11 inches while the length was 17 inches.

THE SURFACES Both surfaces were very smooth and showed no cracks nor flaws of appreciable extent. They were permeated with small air holes but the texture of the tile as a whole was fine grained and smooth. The surfaces were a deep tan in color and even throughout. By a comparison of the texture, hardness and looks of this sample with that of the other samples tested, it would seem probable that the composition of all the forms was the same.

THE SETTING The setting for this sample was somewhat different from that employed for the other samples inasmuch as the thickness of this sample was such that it would not facilitate the building of a wall equal in thickness to the sample. The sample was placed in a wall of ordinary brick four inches thick with the unexposed surface flush with the back of the wall.

The calorimeter was then placed against the unexposed surface of the sample and a pyrometer inserted so as to be in direct contact with the tile. The water and electrical connections were then made and the ordinary procedure followed. Readings of the temperatures were taken at five minute intervals because the thickness of the sample was such that the heat was transmitted at a much faster rate than in other tests.

PHYSICAL CHARACTERISTICS AFTER EXPOSURE

CHANGES

The character of this sample was affected in only a few ways by exposure to fire. There was only a slight change in color, the change being a slight decrease in the reddish tint. The soundness was affected only a trifle, as the sample when struck gave forth a fair metallic ring. No vitrification or calcination could be noticed. No cracks nor flaws other than those present before exposure were to be seen.

TECHNICAL INFORMATION WITH CAPTION

The character of this section was selected in
 only a few ways by reference to the first
 and with a slight change in color, the second and third
 because in the reading light. The second and third only a
 little, as the reader would have found a fair metallic
 tint. No verification or calculation could be made, as
 occurs for the other than the second before always was
 to be used.

TEST #2
Miscellaneous Data

Pyrometers:- #1 = Calibration curve #2 for pyrometer #128

1st Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 4.05°F

Weight of water discharged
= 58.71# in 14 minutes
= 4.19#/min.

2nd Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 6.03°F

Weight of water discharged
= 61.656# in 14 minutes
= 4.40#/min.

3rd Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 8.10°F

Weight of water discharged
= 61.609# in 14 minutes
= 4.40#/min.

Table 2
Water Discharge

Pyrometer: - #1 = Calibration curve "2" for Pyrometer J18

1st Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 4.0°F

Weight of water discharged
= 20.7 lb in 14 minutes
= 1.48 lb/min.

2nd Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 6.8°F

Weight of water discharged
= 21.5 lb in 14 minutes
= 1.54 lb/min.

3rd Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 8.1°F

Weight of water discharged
= 21.0 lb in 14 minutes
= 1.50 lb/min.

TEST #2
Calculations

1st Saturation Point

Furnace temperature = 1201
 Temperature at back of tile = 264
 Difference in temperature = 937

Difference in temperature between entrance and exit of
 calorimeter = 4.0°F
 Rate of flow thru calorimeter = $4.194\frac{\#}{\text{min.}}$

Heat transmitted = $1.834 \times 4.194 \times 4.0^{\circ}$
 = $31.03 \text{ Btu/sq.ft./min.}$

Thermal Conductivity, K, = $\frac{31.03 \times 1.088}{937}$
 = $.03^{\circ}7$

2nd Saturation Point

Furnace temperature = 1281
 Temperature at back of tile = 340
 Difference in temperature = 1241

Difference in temperature between entrance and exit of
 calorimeter = 6.03°F
 Rate of flow thru calorimeter = $4.403\frac{\#}{\text{min.}}$

Heat transmitted = $1.834 \times 4.403 \times 6.03$
 = $48.5^{\circ} \text{ Btu/sq.ft./min.}$

Thermal conductivity, K, = $\frac{48.5^{\circ} \times 1.088}{1241}$
 = $.0422$

3rd Saturation Point

Furnace temperature = 1922
 Temperature at back of tile = 391
 Difference in temperature = 1531

Difference in temperature between entrance and exit of
 calorimeter = 8.10°F
 Rate of flow thru calorimeter = $4.40\frac{\#}{\text{min.}}$

Heat transmitted = $1.834 \times 8.10 \times 4.40$
 = $65.22 \text{ Btu/sq.ft./min.}$

Thermal conductivity, K, = $\frac{65.22 \times 1.088}{1531}$
 = $.0460$

1st Calculation Point

Furnace temperature = 1201
 Temperature at back of tile = 382
 Difference in temperature = 819
 Difference in temperature between entrance and exit of calorimeter = 4.07
 Rate of flow thru calorimeter = 1.132/min.
 Heat transmitted = 1.854 x 1.132 x 4.07
 = 21.03 Btu/hr.ft.².in.
 Thermal conductivity, k , = $\frac{21.03 \times 1.132}{819}$
 = 0.0287

2nd Calculation Point

Furnace temperature = 1201
 Temperature at back of tile = 382
 Difference in temperature = 819
 Difference in temperature between entrance and exit of calorimeter = 4.07
 Rate of flow thru calorimeter = 1.132/min.
 Heat transmitted = 1.854 x 1.132 x 4.07
 = 21.03 Btu/hr.ft.².in.
 Thermal conductivity, k , = $\frac{21.03 \times 1.132}{819}$
 = 0.0287

3rd Calculation Point

Furnace temperature = 1325
 Temperature at back of tile = 381
 Difference in temperature = 944
 Difference in temperature between entrance and exit of calorimeter = 8.16
 Rate of flow thru calorimeter = 4.40/min.
 Heat transmitted = 1.854 x 4.40 x 8.16
 = 67.12 Btu/hr.ft.².in.
 Thermal conductivity, k , = $\frac{67.12 \times 4.40}{944}$
 = 0.0307

T E S T N O . 3

SPECIAL FORM OF TILE MADE
TO SPECIFICATIONS.

This test was made on a special form of tile as shown in Illustration # VI. The grade and quality of the tile used was the same as that used in the three other tests.

1917-18

THE STATE OF NEW YORK

IN SENATE

January 1, 1918.
 The following bill was introduced
 by Senator [Name] and
 passed the Senate on [Date].
 The bill was then sent to the
 Assembly for their consideration.
 The bill was passed by the
 Assembly on [Date].

PHYSICAL CHARACTERISTICS BEFORE EXPOSURE

AND SETTING

THE FORM The form used in this test was made of four slabs of tile with dimensions shown in Illustration No. VI. The slabs were smooth in appearance and of the same color, texture and hardness. Each slab was separated by ribs at either end made of long strips of tile embedded in cement mortar. When completed the form looked like an ordinary piece of building tile with three air spaces.

EXPOSED SURFACE The surface that was exposed to the fire was comparatively smooth in appearance with a deep reddish brown color. The entire surface was somewhat indented with black spots varying in size from one-sixteenth to three-sixteenths inches. A few small chips had been broken from the surface, but the damage was very slight. On one edge of the sample a very slight crack was noticeable, but the remainder of the flange was unmarred. When struck it gave forth a sharp metallic ring.

UNEXPOSED SURFACE The back flange of the sample was very smooth but, like the exposed flange, was somewhat indented with small black spots. The color of this flange was a little more yellow than the exposed surface. The other two flanges possessed the same characteristics as did the back flange. The texture of the slabs was the same as shown where the edges were broken or scarred. The material used in their manufacture was fine except for small pebbles, distributed throughout, which were less than one-eighth inch in diameter.

THE SETTING The setting, on account of the thickness of this sample, was a little different than that used in the other tests. It was found necessary to place four and one-half inch bricks on all sides. Layers of these bricks were used for a considerable distance from the sample, and then ordinary brick was used for filling the remainder of the panel. To prevent any possibility of the exposed surface falling away from the sample, it was deemed necessary to use some means of binding the flanges together. The means adopted consisted of placing two right angle irons, one on each side of the exposed face and embedding them in the brick-work for a distance of three inches. Pyrometers were placed on the face of each slab nearest the calorimeter. The water and electrical connections were then made and the test conducted as given in Test No. 1.

PHYSICAL CHARACTERISTICS AFTER EXPOSURE

CHANGES

The texture of the exposed surface was not appreciably changed but there was a decided change in color, having changed to a deep brown. A few small additional chips had been broken off but otherwise the surface was the same as before exposure. Calcination and vitrification were noticed only in the first flange, the remaining flanges of the form not being affected by fire.

THEORY OF THE EARTH'S CRUST

CHANGES
The texture of the exposed surface was not
appreciably changed but there was a slight
alteration in color, having changed to a light brown. A few small
effluential chips had been broken off but otherwise the surface
was the same as before. No other changes were noticed.
were noticed only in the first place, the remaining changes
of the form not being noticed by the eye.

TEST #3
Miscellaneous Data

Pyrometers:- #1 = calibration curve #4 for pyrometer #131
 #2 = calibration curve #2 for pyrometer #128
 #3 = calibration curve #3 for pyrometer #130
 #4 = calibration curve #5 for pyrometer #Series 5

1st Saturation Point

Difference in temperature between entrance and exit of
 calorimeter = 2.95°F

Weight of water discharged
 = 70.71# in 16.25 minutes
 = 4.35#/min.

2nd Saturation Point

Difference in temperature between entrance and exit of
 calorimeter = 4.65°F

Weight of water discharged
 = 59.23# in 16 minutes
 = 3.70#/min.

3rd Saturation Point

Difference in temperature between entrance and exit of
 calorimeter = 6.11°F

Weight of water discharged
 = 55.92# in 15 minutes
 = 3.72#/min.

TABLE 1
CALCULATION OF

Calibration curve #2 for thermometer 101	2	-
Calibration curve #3 for thermometer 101	3	-
Calibration curve #4 for thermometer 101	4	-

CALCULATION OF

Difference in temperature between surface and soil of
calorimeter = 2.10°C

Weight of water discharged

7.71 in 10 minutes
= 4.626/min

CALCULATION OF

Difference in temperature between surface and soil of
calorimeter = 4.44°C

Weight of water discharged

7.83 in 10 minutes
= 4.758/min

CALCULATION OF

Difference in temperature between surface and soil of
calorimeter = 6.11°C

Weight of water discharged

7.71 in 10 minutes
= 4.758/min

TEST #3
Calculations

1st Saturation Point

Furnace temperature	=	1210
Temperature at back of tile	=	97
Difference in temperature	=	1113
Difference in temperature between entrance and exit of calorimeter	=	2.9°F
Rate of flow thru calorimeter	=	$4.3\frac{\#}{\text{min.}}$
Heat transmitted	=	$1.834 \times 4.3 \times 2.9$ $= 23.5 \text{ Btu/sq.ft./min.}$
Thermal conductivity, K,	=	$\frac{21.6 \times 4.59}{1113}$ $= .097$

2nd Saturation Point

Furnace temperature	=	1500
Temperature at back of tile	=	133
Difference in temperature	=	1367
Difference in temperature between entrance and exit of calorimeter	=	4.6°F
Rate of flow thru calorimeter	=	$3.70\frac{\#}{\text{min.}}$
Heat transmitted	=	$1.834 \times 3.70 \times 4.6$ $= 31.5 \text{ Btu/sq.ft./min.}$
Thermal conductivity, K,	=	$\frac{28.8 \times 4.59}{1367}$ $= .105$

3rd Saturation Point

Furnace Temperature	=	1831
Temperature at back of tile	=	144
Difference in temperature	=	1687
Difference in temperature between entrance and exit of calorimeter	=	6.11°F
Rate of flow thru calorimeter	=	$3.72\frac{\#}{\text{min.}}$
Heat transmitted	=	$1.834 \times 3.72 \times 6.11$ $= 4.16 \text{ Btu/sq.ft./min.}$
Thermal conductivity, K,	=	$\frac{49.5 \times 4.59}{1687}$ $= .114$

Table 1
Calculation

For Section 101

Surface temperature = 121
 Temperature at back of tile = 97
 Difference in temperature = 24
 Difference in temperature between entrance and exit of calorimeter = 2.3
 Rate of flow thru calorimeter = 4.75 l/min
 Heat transmitted = 1.034 x 4.75 x 2.3 = 11.37
 Thermal conductivity, K, = $\frac{11.37}{121 - 97} \times 4.75$
 = 2.07

For Section 102

Surface temperature = 120
 Temperature at back of tile = 103
 Difference in temperature = 17
 Difference in temperature between entrance and exit of calorimeter = 4.7
 Rate of flow thru calorimeter = 3.75 l/min
 Heat transmitted = 1.034 x 3.75 x 4.7 = 18.37
 Thermal conductivity, K, = $\frac{18.37}{120 - 103} \times 3.75$
 = 4.07

For Section 103

Surface temperature = 103
 Temperature at back of tile = 103
 Difference in temperature = 0
 Difference in temperature between entrance and exit of calorimeter = 6.1
 Rate of flow thru calorimeter = 3.75 l/min
 Heat transmitted = 1.034 x 3.75 x 6.1 = 23.87
 Thermal conductivity, K, = $\frac{23.87}{103 - 103} \times 3.75$
 = 114

T E S T N O . 4

SPECIAL FORM OF TILE MADE

TO SPECIFICATIONS

This test was made on a special form of tile similar in make-up to that used in the third test.

THE

AMERICAN

TO

THIS BOOK WAS MADE BY THE
 AMERICAN BOOK CONCERN
 IN NEW YORK

PHYSICAL CHARACTERISTICS BEFORE EXPOSURE

AND SETTINGS

- THE FORM The form used in this test was made of four slabs of tile with dimensions as shown on Illustration No. VI. The slabs were smooth in appearance and of the same color, texture and hardness. Each slab was separated by ribs at either end, made of long strips of tile embedded in cement mortar. When completed the form looked like an ordinary piece of building tile with three air spaces.
- EXPOSED SURFACE The exposed surface of the form was smooth in appearance. No large air holes were present but the flange was porous throughout. The predominating color was reddish brown but in one corner the color was a light yellow. In a few places small chips had been broken off but the damage was not sufficient to cause any discrepancies in the results.
- UNEXPOSED SURFACE The unexposed surface of the sample was a light yellow in color over about one-half of its area and an orange color over the other half. The flange was smooth and solid throughout. The ends, sides, and faces of the sample were square.
- THE SETTING The sample was placed in a wall of ordinary brick laid edgeways, the unexposed surface of the sample being laid flush with the outer edge of the wall. The calorimeter was placed in contact with the surface of the sample. The pyrometers were then inserted and the water and electrical connections made. The procedure as outlined in Test No. 1 was then followed. Readings of Pyrometers and temperatures were taken every fifteen minutes.

THEORY OF THE EARTH AND ITS HISTORY

The exposed surface of the earth is not a uniform one. It is a surface of great complexity, and its features are the result of a long and varied history. The surface of the earth is divided into two main parts, the land and the water. The land is further divided into mountains, hills, and valleys. The water is divided into oceans, seas, and rivers. The surface of the earth is also divided into different climates, and these are the result of the different positions of the land and water.

TEST #4
bMiscellaneous Data

Pyrometers:- #1 = calibration curve #4 for pyrometer #131
 #2 = calibration curve #2 for pyrometer #128
 #3 = calibration curve #3 for pyrometer #130
 #4 = calibration curve #6 for pyrometer #Series 5

1st Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 1.26°F

Weight of water discharged = $55.02\frac{\#}{\text{min}}$ in 20 minutes
= $2.75\frac{\#}{\text{min}}$.

2nd Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 2.01°F

Weight of water discharged = $61.06\frac{\#}{\text{min}}$ in 25 minutes
= $2.44\frac{\#}{\text{min}}$.

3rd Saturation Point

Difference in temperature between entrance and exit of
calorimeter = 2.43°F

Weight of water discharged = $43.73\frac{\#}{\text{min}}$ in 13 minutes
= $3.36\frac{\#}{\text{min}}$.

1.1 = calibration curve for pyrometer
 1.2 = calibration curve for pyrometer
 1.3 = calibration curve for pyrometer
 1.4 = calibration curve for pyrometer

1st Station Point

Difference in temperature between entrance and exit of
 calorimeter = 1.30°
 Weight of water discharged = 77.32 in 30 minutes
 = 2.57 (lb/min)

2nd Station Point

Difference in temperature between entrance and exit of
 calorimeter = 2.01°
 Weight of water discharged = 61.66 in 30 minutes
 = 2.05 (lb/min)

3rd Station Point

Difference in temperature between entrance and exit of
 calorimeter = 2.42°
 Weight of water discharged = 43.32 in 30 minutes
 = 1.44 (lb/min)

TEST NO. 4
Calculations

1st Saturation Point

Furnace temperature = 1230
Temperature at back of tile = 80
Difference in temperature = 1150

Difference in temperature between entrance and exit of
calorimeter = 1.26°F
Rate of flow thru calorimeter = 2.75#/min.

Heat transmitted = 1.834 x 2.75 x 1.26
= 6.33 Btu/sq.ft./min.

Thermal conductivity, K, = $\frac{6.33 \times 7.545}{1150}$
= .0415

2nd Saturation Point

Furnace temperature = 1537
Temperature at back of tile = 95
Difference in temperature = 1442

Difference in temperature between entrance and exit of
calorimeter = 2.01°F
Rate of flow thru calorimeter = 2.44#/min.

Heat transmitted = 1.834 x 2.44 x 2.01
= 8.96 Btu/sq.ft./min.

Thermal conductivity, K, = $\frac{8.96 \times 7.545}{1442}$
= .0468

3rd Saturation Point

Furnace temperature = 1872
Temperature at back of tile = 134
Difference in temperature = 1738

Difference in temperature between entrance and exit of
calorimeter = 2.43°F
Rate of flow thru calorimeter = 3.36#/min.

Heat transmitted = 1.834 x 3.36 x 2.43
= 11.28

Thermal Conductivity, K, = $\frac{11.28 \times 7.545}{1738}$
= .049

Int. Station Point

Furnace temperature = 1230
 Temperature at back of tile = 80
 Difference in temperature = 1150
 Difference in temperature between entrance and exit of calorimeter = 1.20°
 Rate of flow thru calorimeter = 2.77 g/min.
 Heat transmitted = $1.884 \times 2.77 \times 1.20$
 = 6.33 Btu/hr.
 Thermal conductivity, k , = $\frac{6.33 \times 7.71}{1150}$
 = .0417

Int. Station Point

Furnace temperature = 1230
 Temperature at back of tile = 90
 Difference in temperature = 1140
 Difference in temperature between entrance and exit of calorimeter = 2.01°
 Rate of flow thru calorimeter = 2.77 g/min.
 Heat transmitted = $1.884 \times 2.77 \times 2.01$
 = 8.30 Btu/hr.
 Thermal conductivity, k , = $\frac{8.30 \times 7.71}{1140}$
 = .0438

Int. Station Point

Furnace temperature = 1230
 Temperature at back of tile = 134
 Difference in temperature = 1096
 Difference in temperature between entrance and exit of calorimeter = 2.40°
 Rate of flow thru calorimeter = 2.77 g/min.
 Heat transmitted = $1.884 \times 2.77 \times 2.40$
 = 11.98
 Thermal conductivity, k , = $\frac{11.98 \times 7.71}{1096}$
 = .047

Calculation

1st Calculation Point

Temperature at back of tile = 1230
 Difference in temperature = 50
 Difference in temperature between entrance and exit of calorimeter = 1.200
 Rate of flow thru calorimeter = 2.75 l/min.
 Heat transmitted = $1.834 \times 2.75 \times 1.20$
 = 6.31 kcal/min.
 Thermal conductivity, k = $\frac{6.31 \times 7.62}{11.50}$
 = 4.15

2nd Calculation Point

Temperature at back of tile = 1287
 Difference in temperature = 92
 Difference in temperature between entrance and exit of calorimeter = 2.075
 Rate of flow thru calorimeter = 2.75 l/min.
 Heat transmitted = $1.834 \times 2.75 \times 2.07$
 = 10.38 kcal/min.
 Thermal conductivity, k = $\frac{10.38 \times 7.62}{14.42}$
 = 5.468

3rd Calculation Point

Temperature at back of tile = 1287
 Difference in temperature = 134
 Difference in temperature between entrance and exit of calorimeter = 2.437
 Rate of flow thru calorimeter = 2.75 l/min.
 Heat transmitted = $1.834 \times 2.75 \times 2.43$
 = 11.98
 Thermal conductivity, k = $\frac{11.98 \times 7.62}{17.86}$
 = 5.07

CHAPTER V.

CONCLUSIONS

REVISED

REVISED

PRELIMINARY DISCUSSION

DEFINITION

Suppose we have a slab of tile of unit thickness with one face at a temperature of T^0 and the other face at a temperature of $(T-1)^0$. The quantity of heat which passes per unit of time through each unit of area of the tile is called the Thermal Conductivity of the tile. In its most simple form the law can be expressed best as follows:

$$H = \frac{ktA(T_2 - T_1)}{L}$$

where

H = quantity of heat transmitted

K = proportionality factor, depending upon the substance, and is called the coefficient of thermal conductivity.

t = increment of time during which the process continues.

A = area of cross-section through which the heat passes.

$T_2 - T_1$ = temperature difference between the two surfaces.

L = thickness of the material.

APPLICATION

In the tests herein described it has been the aim of the writer to devise a method whereby they could measure H, the quantity of heat transmitted. As an accurate and precise measurement of this heat was anticipated as impossible, the apparatus was developed with the idea of eliminating most of the gross efficiency losses, and obtaining results which could be used in a relative study of the various forms. Each test was made under the same conditions, and therefore, the heat measured was at least proportional to the total heat in each test and the results obtained can be said to be relative. In either case, whether the losses are a constant quantity or whether percentages of the whole, the relativity of the results would be unchanged.

IMPROVEMENTS

As stated previously, the results obtained in this thesis are not absolutely accurate, and at this point, a word might be said as to new ideas which may be incorporated in a new and better design of calorimeter. It is suggested that the calorimeter be made smaller, preferably elliptical in shape, with major and minor axes of ten inches and seven inches respectively. The annular ring, if made with its major and minor axes equal to thirteen inches and ten inches respectively, will provide a means of insulation for the sides of the calorimeter that will be as perfect, under the operating conditions, as is possible. The remaining features of construction can be made the same as those in the calorimeter used in this thesis, and it is felt that a calorimeter constructed on these lines will furnish the most accurate means for the measurement of heat transmitted through various materials.

GENERAL CONCLUSIONS

TIME- TEMPERATURE

The time-temperature curves for all of the samples tested show but a few individual characteristics that can be called worthy of mention. It is to be noticed that Curve C of Curve #7 and Curve C of Curve #13 have a slope quite different at one point than any of the other curves. This point is at the temperature of 212° Fahrenheit. From these curves it can be seen that the temperature remains constant for a considerable period of time at this point, which, in all probability, is due to the presence of an appreciable amount of moisture, which, until driven off, would keep the temperature constant at this point. The absence of this characteristic on the other curves can probably be traced to the rapid rise in temperature at this point, this rise being of such degree as to drive the moisture from the sample at a very short interval of time.

The curve of the furnace temperatures for each test shows, in general but little variation. Some question might arise as to the saturation points obtained in some cases, but it can be stated here that the furnace temperatures, in some instances, varied considerably and thereby caused a change in temperature throughout the sample. These changes, particularly at points of saturation, were carefully noted, and, during the period when it seemed that the temperatures were becoming constant, readings were continually taken between intervals in order to insure absolutely accuracy in regard to the temperatures taken as saturation temperatures. In general, however, the slope of all the curves at saturation temperatures is horizontal.

TEST #1 Curves A and C of Curve #7 give some idea of the value of confined air spaces in building tile, the temperature difference through an air space of 2.48 inches being from 250° to 300°. Another peculiar characteristic to be noted is the unequal differences in temperature between, first, Curve A and curve of furnace temperatures, and, second, Curve B and Curve Z. This difference of the differences varies from 100° to 200°, and to what this difference can be traced is a question that cannot, at present, be answered.

TEST #3 A fact to be noted in regard to the curves
TEST #4 shown for special samples #1 and #2 is the higher temperatures throughout, for the same furnace temperatures. This is due to the smaller air spaces and the thinner flanges, but no definite conclusion at this point can be drawn as to the relative value of either of these factors. The fact remains however that the larger the air spaces and the thicker the flanges the less will be the temperatures throughout, and, also, the transmission of heat, per unit of area, will be less.

Another factor to be noted is the relation between the temperature shown in Curves A and C on Curve #7 and those shown in Curves A and D on Curves #13 and #16. It will be seen that Curve A of Curve #7 is lower than the corresponding curves on Curve #13 and #16, and also, that Curve C is higher than those shown on Curves #13 and #16. This might be reasonably explained by the presence of the webs in the sample used in Test #1, for, as conducting agents which were better than the air between the inner and outer flanges, these webs would transmit heat from one flange to another with such rapidity as to cause appreciable decrease of temperature at one face and an appreciable increase at the other.

Btu. CURVES The Btu.-Difference in temperature curves for the four tests show very clearly the limits of accuracy of the calorimeter. The shape of all the curves is practically a straight line, but the limits of accuracy are about 400° Fahrenheit in all cases, that is, for a difference in temperature of about 400° or less, the calorimeter used in these tests is not sensitive enough to measure the heat transmitted. It will be seen therefore that the amount of heat transmitted can only be compared relatively with that transmitted through the other sample, but, since the degree of accuracy is approximately the same in all cases, the comparison of these relative values is correct.

K - CURVES The K -Difference in temperature curves show, in all cases but one, a slope that is peculiar. Whether this is due to the presence of the air spaces or to various other factors, cannot at this stage of the research be stated. By observing Curve #9 it will be seen that the curve passes through absolute Zero. This is the ideal curve, but in the other three tests it will be noticed that the curve has a much different slope. Curve #12, showing K plotted against difference in temperature, comes the closest to conforming to the ideal curve, and it is probable that with more refined methods this curve would become the ideal curve for thermal conductivity. The thermal conductivity of any material increases directly in proportion to the temperature, and thus forms a straight line passing through absolute zero. Whether this is a condition that is obtainable when different conducting agents are placed in series with each other, as the air and tile in the special forms, is a question that is at present not capable of being answered. The thermal conductivity of air and tile are different, and whether the combination of them under the conditions present in these tests would produce an ideal curve is a question which can be answered only by further tests on samples similar to those used in this thesis.

17. To establish a preliminary as to the nature of the
line and the thickness, the following was done from the
as containing these lines were taken from the
by the removal of the line in the area of the line
down on Curve 13 and 14. This might be reasonably explained
Curve 13 and 14, and also that Curve 15 is higher than those
Curve 16 of Curve 17 is lower than the corresponding curves
in Curve 18 and 19. It will be seen that
the line in Curve 18 and 19 is of a different
thickness than the line in Curve 17. The variation in the

VALUE AS
FIREPROOFING

As to value as fireproofing materials, a generality may be stated which will cover all the samples tested. By assuming a sample of solid tile equal in thickness to each of the samples, and calculating, from the general heat equation, the quantity of heat transmitted through each of these solid samples, it will be seen that, in every case, the heat transmitted through the solid sample is less than that transmitted through the sample to which it is equal in thickness. The difference between the amounts of heat transmitted through the samples of solid tile and the other samples varies, but this amount is least in case of special form #2 used in Test #4. By comparing this test with that of special form #1, it can be seen that the larger the air spaces, the greater the resistance to the transmission of heat, and therefore the more valuable is that form as a fireproofing material. This is further substantiated by referring to results of Test #1, although, in this case, the results cannot be absolutely compared, because of the presence of webs of tile in this form.

It would seem, therefore, that, disregarding for the moment the factors of expense and the difficulties encountered when used as a material for building construction, tile of the solid form is the best for use as a fireproofing material. The introduction of air spaces in the design of any form will materially decrease the value of that form as a fireproofing material, but, if air spaces are to be introduced in the design, it would seem advisable that these air spaces be made as large as practicable.
